Received 20 December 2001/Accepted 22 April 2002

Analysis of potential virulence factors of oral spirochetes focuses on surface and secreted proteins. The *Treponema denticola* chymotrypsin-like protease (CTLP) is implicated in degradation of host cell molecules and contributes to tissue invasion. The CTLP complex, composed of the 72-kDa PrtP protein and two auxiliary proteins with molecular masses of approximately 40 and 30 kDa, is also involved in localization and oligomerization of the *T. denticola* major surface protein (Msp). The larger auxiliary protein was reported to be encoded by an open reading frame (ORF2) directly upstream of *prtP*. The deduced 39-kDa translation product of ORF2 contains a sequence matching the N-terminal sequence determined from one of the CTLP complex proteins. No proteins with significant homology are known, nor was information available on the third protein of the complex. DNA sequence analysis showed that ORF2 extended an additional 852 bp upstream of the reported sequence. The complete gene, designated prcA, encodes a predicted N-terminally-acetylated polypeptide of approximately 70 kDa. Isogenic mutants with mutations in *prtP*, *prcA*, and *prcA-prtP* all lacked CTLP protease activity. The *prcA* mutant lacked all three CTLP proteins. The *prcA-prtP* mutant produced only a C-terminally-truncated 62-kDa PrcA protein. The *prtP* mutant produced a full-length 70-kDa PrcA. Immunoblot analysis of recombinant PrcA constructs confirmed that PrcA is cleaved to yield the two smaller proteins of the CTLP complex, designated PrcA1 and PrcA2. These data indicate that PrtP is required for cleavage of PrcA and suggest that this cleavage may be required for formation or stability of outer membrane complexes.

Analysis of potential virulence factors of oral spirochetes focuses on surface and secreted proteins (reviewed in reference 8). The surface-expressed chymotrypsin-like protease (CTLP) is implicated in *Treponema denticola* cytotoxicity (6), degradation of fibronectin (5, 28) and host cell protease inhibitors (13), and detachment of cultured cells (28). By disrupting intercellular junctions (4), CTLP has been shown to mediate migration of *T. denticola* through model basement membranes (14) and increase permeability of a multilayer epithelial cell model (28).

Studies of isogenic *T. denticola* mutants indicated that a relationship exists between CTLP activity and expression of another potential virulence factor of this organism, the pore-forming major surface protein (Msp) (6). *T. denticola* MPE, a defined *msp* mutant expressing a C-terminally-truncated Msp monomer, produced no CTLP complex proteins or protease activity (10). Two previous studies reported construction of isogenic *prtP* mutants: strain K1, carrying an *ermF/AM* cassette inserted in *prtP* (18); and strain CKE, in which an *ermF/AM* cassette replaces a *KpnI* fragment that includes the 3′ end of *prcA* and the 5′ end of *prtP* (10). Both mutants exhibited defects in Msp production levels and oligomerization, in addition to the expected lack of PrtP protease activity. The connection between Msp expression and CTLP activity appears to be posttranscriptional (J. C. Fenno, unpublished results), suggesting that Msp and one or more proteins of the CTLP complex are required for proper localization or formation of native outer membrane complexes.

Native CTLP, a detergent-stable complex with an apparent molecular mass of 95 kDa, resolves to three polypeptides upon heating. The largest, the 72-kDa protein PrtP (dendilisin) encoded by *prtP*, exhibits homology with the *Bacillus subtilis* serine protease subtilisin (19). The *prtP* gene and its activity are conserved among several species of oral treponemes (17). Isogenic *prtP* mutants lack CTLP activity (10, 18). The sizes of the two smaller proteins of the CTLP complex have been variously reported as 27 and 23 kDa (27), 39 and 32 kDa (22), and 43 and 38 kDa (19), resulting in some confusion as to the identity and composition of the protease complex.

An open reading frame (ORF) designated ORF2 directly upstream of *prtP* has been proposed to encode the larger of the two auxiliary proteins of the CTLP complex (19). One of the two N-terminal amino acid sequences that can be determined from native CTLP (19; D. Grenier, personal communication) matches a sequence in the deduced amino region of the ORF2 peptide (19). No proteins with homology to the deduced 39-kDa product of ORF2 are known. Although ORF2 is cotranscribed with *prtP* and insertional mutagenesis of ORF2 results in loss of PrtP activity (K. Ishihara, H. K. Kuramitsu, T. Miura, and K. Okuda, Abstr. 79th Meet. Int. Assoc. Dent. Res., abstr. 941, 2001), no studies have directly confirmed the identities of the two protease-associated proteins or characterized their activities. The present study identifies the complete sequence of the gene encoding a protease-associated protein and de-
scribe a novel posttranslational processing event mediated by PrtP.

MATERIALS AND METHODS

Bacterial strains, plasmids, and growth conditions. T. denticola ATCC 35405 and isogenic mutants (Table 1) were grown and maintained in NOS broth medium as previously described (16), with erythromycin (40 μg ml⁻¹) added as appropriate. For allelic replacement, mutants were selected on NOS/GN plates (3) containing erythromycin (40 μg ml⁻¹) as described previously (10, 21). Cultures were examined by phase-contrast microscopy for purity and typical strain morphology before use.

Escherichia coli strains JM109 (30) and TOP10 (Invitrogen, Carlsbad, Calif.) were used as hosts for routine subcloning and plasmid preparations. E. coli NovBl2 (Novagen) was used as a strain for direct cloning of PCR fragments in plasmid vector pSTBlue-1 (Novagen). Plasmid pCTLP (10) carries a NovaBlue (Novagen) cassette PCR fragment and was used as a vector for routine subcloning and plasmid preparations.

Chemicals. Unless otherwise noted, chemicals were purchased at the highest available purity from Sigma Chemical Co. (St. Louis, Mo.) or Fisher Scientific (Chicago, Ill.).

Recombinant DNA methods. Unless stated otherwise, standard methods described by Ausubel et al. (2) or Sambrook et al. (26) were followed. DNA fragments were eluted from agarose gels with the Gene Clean II kit (Bio101, La Jolla, Calif.). Genomic and plasmid DNA were isolated with the Wizard Genomic DNA Purification kit and Wizard Plus SV Miniprep kit (Promega, Madison, Wis.), respectively. Oligonucleotide primers (Invitrogen, Carlsbad, Calif.) were designed by using the GeneFisher algorithm (12). For Southern blot analysis, DNA fragments were digested with restriction endonucleases and transferred to nylon membranes (Immobion-Ny; Millipore) and hybridized with fluorescent-labeled DNA probes, followed by incubation of the blots with streptavidin, as described previously (21).

For expression studies, DNA fragments of interest were cloned in-frame with the T7 Gene 10 leader sequence in pET17b (Novagen). Oligonucleotide primers KX34 and KX35 (Table 2) complementary to the 5’ and 3’ ends of ORF2, with specific restriction sites added for cloning in pET17b, were used to amplify the predicted ORF2 coding region from T. denticola genomic DNA. The BamHI-XhoI-digested PCR product was gel purified and cloned in pET17b, yielding pCT88. Similarly, the PCR product amplified with CX252 and CX259 (Table 2) was digested to yield BamHI-ScaI-Stop, BamHI-SnaI, or BamHI-MspAI fragments, which were gel purified and cloned in pET17b, yielding pSY132, pSY133, and pSY134, respectively (Fig. 1A).

For mutagenesis of prtP, a 610-bp ClaI-SmaI fragment of plasmid pCTLP was gel purified and ligated to the AccI-BstZ17I fragment of pSY120 containing the erm/F AM gene cassette. In the resulting plasmid, pSY130, erm/F AM replaces a 581-bp internal fragment of prtP.

For mutagenesis of praC, the 4-kb EcoRI-BamHI fragment of plasmid pCTLP containing ORF2-prtP was first cloned in pSTBlue-1, yielding pSY119. A PCR product generated with CX260 and CX251 (Table 2) containing all but the first 10 bp of the 5’ end of praC was amplified from T. denticola genomic DNA and cloned in pSTBlue-1, yielding pSY123. The 1-kb XhoI-Ndel fragment of pSY123 containing praC DNA was isolated and digested to yield the 7.5-kb XhoI-Ndel fragment of pSY119, yielding pSY125. pSY125 was linearized at the unique Ndel site in praC and ligated to the Ndel-digested fragment of pSY120 containing erm/F AM, yielding pSY126.

PCR and sequence analysis. Primers and sequence-derived primers, according to the manufacturer’s instructions. DNA sequences were resolved with an Applied Biosystems model 310 automated DNA sequencer. Both strands of the DNA sequence reported here were sequenced in their entirety. Analysis of DNA sequence data was performed with SeqEd 1.0 (Applied Biosystems, Inc.) and DNA Strider (Service de Biologie, Energie Atomique, Saclay, France). The nonredundant SWISS-PROT, PIR, EMBL and GenBank databases were searched for homologous peptide and sequence-derived primers, according to the manufacturer’s instructions.

DNA sequence analysis. Templates for DNA sequencing included plasmid DNA and PCR products. Sequencing reactions were performed with ABI PRISM BigDye Terminator Cycle Sequencing kits with fluorescent-labeled dyeoxynucleoside triphosphates (Applied Biosystems, Inc., Foster City, Calif.) and sequence-derived primers, according to the manufacturer’s instructions. DNA sequences were resolved with an Applied Biosystems model 310 automated DNA sequencer. Both strands of the DNA sequence reported here were sequenced in their entirety. Analysis of DNA sequence data was performed with SeqEd 1.0 (Applied Biosystems, Inc.) and DNA Strider (Service de Biochimie, Centre National de Biotechnologie Information, Bethesda, Md.). Protein sequence motifs were searched for homologous peptide and sequence-derived primers, according to the manufacturer’s instructions. DNA sequences were resolved with an Applied Biosystems model 310 automated DNA sequencer. Both strands of the DNA sequence reported here were sequenced in their entirety. Analysis of DNA sequence data was performed with SeqEd 1.0 (Applied Biosystems, Inc.) and DNA Strider (Service de Biochimie, Centre National de Biotechnologie Information, Bethesda, Md.). Protein sequence motifs were searched for homologous peptide and sequence-derived primers, according to the manufacturer’s instructions.
introduced into T. denticola were UV irradiated at 25 mJ cm\(^{-2}\) as described by Picardeau et al. (25) prior to electroporation.

Preparation of antisera. Polyclonal antisera to the purified native CTLP protein complex and to the recombinant ORF2 polypeptide were raised in New Zealand White rabbits as described previously by intramuscular injections with approximately 1 mg of purified protein in complete Freund’s adjuvant (6, 9, 14). The titers of the antisera were determined by enzyme-linked immunosorbent assay, with alkaline phosphatase-conjugated goat anti-rabbit antibody (1:5,000; Life Technologies, Gaithersburg, Md.). A monoclonal antibody that recognizes the T7 gene 10 leader peptide encoded on pET17b (Novagen) was used as a positive control in expression studies.

Gel electrophoresis and immunoblotting. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and Western immunoblotting were done as described previously (9). E. coli cells were harvested by centrifugation at 10,000 \( \times g \) (10 min, 4°C). The pellets were resuspended in 100 \( \mu l \) of sample buffer containing \( \beta \)-mercaptoethanol and 2 mM phenylmethylsulfonyl fluoride. Whole-cell extracts or the detergent phase of Triton X-114 extracts of T. denticola cells were prepared as described previously (6). Samples were heated at 100°C for 5 min prior to electrophoresis in 8 to 16% gradient gels. Proteins in gels were detected by Coomassie brilliant blue staining. Proteins blotted to nitrocellulose membranes were probed with rabbit polyclonal primary antibodies followed by horseradish peroxidase-conjugated goat anti-rabbit immunoglobulin G (IgG) or goat anti-mouse IgG (Pierce Chemical Co., Rockford, Ill.) as appropriate. Protein bands of interest were developed with SuperSignal West Pico chemiluminescent substrate (Pierce) and detected with a Fluor-S Multi-Imager (Bio-Rad). For reprobing, blots were incubated in stripping buffer (2% SDS, 62.5 mM Tris-HCl [pH 6.8], 10 mM \( \beta \)-mercaptoethanol; 60°C, 30 min) and washed as suggested by the SuperSignal West Pico kit protocol (Pierce).

Enzymatic activity assays. Enzymatic activities of T. denticola parent and mutant strains were tested by hydrolysis of chromogenic substrates succinyl-L-alanyl-L-alanyl-L-prolyl-L-phenylalanine-\( p \)-nitroanilide (SAAPFNA) and \( N \)-\( \beta \)-benzoyl-L-arginine-\( p \)-nitroanilide (BA\( p \)NA) as described previously (7). Four-day cultures were adjusted to an \( A_{600} \) of 0.25 in NOS broth and then diluted 1:8 in deionized water for assays. NOS broth diluted 1:8 in deionized water served as a negative control.

Nucleotide sequence accession number. The nucleotide sequence of T. denticola prcA has been assigned GenBank accession no. AY069957.

RESULTS

Identification of the complete prcA gene. Our previous studies using isogenic T. denticola mutant CKE, which carries a deletion of a KpnI fragment spanning the 3’ end of ORF2 and
the 5’ end of prtP in the CTLP locus (Fig. 1), demonstrated involvement of the CTLP complex in expression and oligomerization of Msp (10). A concurrent study reported similar results for an isogenic prtP mutant (18). To construct other defined mutations in this locus, we designed oligonucleotide primers based on preliminary unannotated contigs of the T. denticola genome (http://www.tigr.org) sequences upstream of the previously reported prtP sequence (19). The preliminary genome sequence data showed that ORF2 upstream of prtP extended an additional 852 bases upstream of the published sequence, suggesting that the previously reported sequence was incomplete. We amplified this upstream region and ORF2 from T. denticola ATCC 35405 genomic DNA using oligonucleotide primers CX251 and CX252 and determined its sequence. The DNA sequence obtained was identical to that of the preliminary genome sequence contig (data not shown).

The newly identified complete gene, designated prcA (for protease complex associated) comprises an ORF of 1,917 nucleotides that could encode a 639-residue polypeptide of approximately 70 kDa (data not shown; GenBank accession no. AY069957), compared with the 39-kDa deduced product of ORF2. The deduced PrcA peptide contains a hydrophobic N-terminal region that could serve as a membrane-targeting or translocation signal. The N-terminal region includes a potential recognition site (L-F-G-S-C, residues 20 to 24 [boxed in Fig. 1]) for spirochetal signal peptidase II (15). Searches of GenBank protein sequences and translated contigs of available tarentid homologues of PrcA fi
determined from one of the native CTLP complex proteins (19, 22, 27), residues 272 and 289 (marked with an asterisk in Fig. 1) are the only potential cleavage sites for PrtP activity. The previously reported deduced peptide product of ORF2 begins at residue 285 (boxed in Fig. 1). The N-terminal sequence determined from one of the native CTLP complex proteins (19; D. Grenier, personal communication) is present in PrcA (residues 316 to 333 [shaded in Fig. 1]).

Construction of isogenic mutants in prcA and prtP. Isogenic mutants in prcA and prtP were constructed by allelic replacement mutagenesis. Plasmids pSY126 and pSY130, containing disrupted prcA and prtP, respectively, were digested with PvuII to separate the vector from insert fragments. T. denticola cells were electroporated with linear DNA from pSY126 or pSY130 and selected for erythromycin resistance. Erythromycin-resistant colonies were isolated, and the structures of the mutant mutants in this locus, we designed oligonucleotide primers based on preliminary unannotated contigs of the T. denticola genome (http://www.tigr.org) sequences upstream of the previously reported prtP sequence (19). The preliminary genome sequence data showed that ORF2 upstream of prtP extended an additional 852 bases upstream of the published sequence, suggesting that the previously reported sequence was incomplete. We amplified this upstream region and ORF2 from T. denticola ATCC 35405 genomic DNA using oligonucleotide primers CX251 and CX252 and determined its sequence. The DNA sequence obtained was identical to that of the preliminary genome sequence contig (data not shown).

Construction of isogenic mutants in prcA and prtP. Isogenic mutants in prcA and prtP were constructed by allelic replacement mutagenesis. Plasmids pSY126 and pSY130, containing disrupted prcA and prtP, respectively, were digested with PvuII to separate the vector from insert fragments. T. denticola cells were electroporated with linear DNA from pSY126 or pSY130 and selected for erythromycin resistance. Erythromycin-resistant colonies were isolated, and the structures of the mutant constructs in strains CCE (prtP mutant) and PNE (prcA mutant) were confirmed by Southern blot analysis. HindIII-digested genomic DNAs of T. denticola strains 35405 (parent), CCE (prtP mutant), CKE (prcA-prtP mutant), and MPE (CTLP-defective msp mutant) (10) were below detectable levels (data not shown). In contrast, there were no significant differences between strains in hydrolysis of BApNA (data not shown), a chromogenic substrate recognized by the OpdB peptidase (7).

Protein expression and processing of PrcA in parent and mutant strains. Expression of PrcA and Msp was assayed in parent and mutant strains. As shown in Fig. 3A, anti-Msp antibodies recognized the large amount of Msp and breakdown products produced in the parent strain, compared with the much smaller amount of Msp produced in the various mutants. Msp was at most barely detectable in strains CCE (prtP mutant, lane 2), PNE (prcA mutant, lane 3) and CKE (prcA-prtP mutant, lane 4). Compared with the parent strain, T. denticola MPE (lane 5) produced a lesser amount of a C-terminally-truncated Msp, as previously reported (8). When probed with anti-ORF2 antisera, no reactive proteins were detected in PNE (prcA mutant, lane 3) or MPE (CTLP-defective msp mutant, lane 5), while a band of 39 kDa corresponding to the size of the larger of the two auxiliary proteins of the protease complex was recognized in 35405. Interestingly, the 39-kDa band was absent in both CCE and CKE, and a higher-molecular-mass band was present in each. The reactive band in CCE migrated at 70 kDa, while in CKE, the reactive band was at 62 kDa. These bands correspond in size to the predicted translation products of prcA in these strains: full-length protein in CCE and truncated protein in CKE. To determine whether the N-terminal region of PrcA was produced in the prcA mutant PNE, the parent and mutant strains were probed with antibodies raised against the native CTLP complex. Immunoreactive bands at 72 kDa (PrtP) and 39 and 32 kDa (CTLP auxiliary proteins) were detected in the parent strain (Fig. 4A, lane 5), while no reactive bands were detected in the mutant PNE (Fig. 4A, lane 6). This indicates that the prcA mRNA is translated as a 70-kDa polypeptide that is then cleaved to the approximately
39-kDa mature protein PrcA2 (Fig. 1) in strains expressing PrtP protease activity. The stability of the PrcA translation product in mutant strains appeared to be dependent on the particular strain construct.

Expression of PrcA in E. coli. To determine whether PrcA might encode both of the two auxiliary proteins of the CTLP complex, PrcA expression in E. coli was studied. Attempts to clone the full-length prcA gene were unsuccessful, suggesting that expression of the hydrophobic N terminus was toxic in E. coli. Several fragments of prcA were expressed as fusion proteins with the T7 gene 10 leader sequence under the control of a T7 RNA polymerase promoter in pET17b (Fig. 1). Fragments of prcA, beginning at the BamH1 site near the 5’ end of the gene (Fig. 1) and ending at recognition sites for Scal (pSY132), SnaBI (pSY133), or MspAI1 (pSY134) were cloned and expressed. The fusion proteins expressed from these plasmids include PrcA residues 36 to 497 (pSY132, 52.3 kDa), 36 to 350 (pSY133, 41 kDa) and 36 to 307 (pSY134, 36 kDa). DNA encoding the predicted 39-kDa ORF2 product (19), which corresponds to residues 285 to 639 of PrcA, was amplified from genomic DNA and similarly cloned in pET17b, yielding pCF38, which encodes a T7-PrcA fusion protein of 41 kDa. The recombinant protein expressed from pCF38 was excised from an SDS-PAGE gel and used to generate polyclonal rabbit antiserum. In Western immunoassays, these antibodies recognized recombinant proteins of the expected sizes expressed from pSY132 and pCF38, respectively (Fig. 4B, lanes 1 and 4). Anti-ORF2 sera did not recognize the recombinant proteins expressed from pSY133 and pSY134, demonstrating that, if the PrcA polypeptide was cleaved to yield the two observed smaller proteins of the CTLP complex, these antibodies would recognize only the protein derived from the C-terminal portion of PrcA. As a positive control, a duplicate blot was probed with a monoclonal antibody directed against the T7 gene 10 leader.

FIG. 3. Western immunoassays showing expression of Msp and PrcA in T. denticola parent and mutant strains. Panel A shows T. denticola strains probed with antiserum raised against recombinant Msp. Panel B shows the same blot probed with antiserum raised against recombinant PrcA2 (ORF2). Lanes: 1, 35405 (parent); 2, CCE (prtP mutant); 3, PNE (prcA mutant); 4, CKE (prcA-prtP mutant); 5, MPE (msp mutant).

FIG. 4. Western immunoassays showing PrcA expression in E. coli strains carrying recombinant PrcA constructs and in the T. denticola parent and prcA mutant. Panel A was probed with antiserum raised against native CTLP complex. The three peptides of the CTLP complex are indicated as follows: asterisk, PrtP; open triangle, PrcA1; and solid triangle, PrcA2. Panel B shows the same blot probed with antiserum raised against recombinant PrcA2 (ORF2). Lanes: 1, E. coli(pSY132); 2, E. coli(pSY133); 3, E. coli(pSY134); 4, E. coli(pCF38); 5, T. denticola 35405; 6, T. denticola PNE (prcA mutant).
peptide. All four recombinant proteins were recognized by this antibody (data not shown). When probed with antibodies raised against the native CTLP complex (Fig. 4A), recombinant T7-PrcA proteins of the predicted sizes were recognized in all four E. coli strains. Anti-CTLP antibodies recognize the three proteins of the CTLP complex in T. denticola 35405 that are absent in the prcA mutant PNE (Fig. 4A, lanes 5 and 6). These data indicate that the amino-terminal region of PrcA comprises the 32-kDa PrcA1, the third protein of the CTLP complex.

**DISCUSSION**

Native expression of two potential virulence determinants of T. denticola, the CTLP protease complex and the Msp protein, appears to be related. We previously reported that, in addition to the expected loss of CTLP protease activity, disruption of the prtP locus results in a greatly decreased ability of T. denticola to produce the native oligomeric form of the major surface protein, Msp (10). We also found an apparently related phenomenon in a defined T. denticola msp mutant that was unable to oligomerize Msp due to a mutation in the C terminus of the Msp peptide and also lacked all detectable CTLP proteins and protease activity (10). The two smaller proteins that form the native CTLP complex with the 72-kDa PrtP protease had no known functions, and in the case of the one protein whose gene had been reported, no known homologues (19).

For this reason, we chose to further characterize these proteins and their potential role(s) in assembly or stability of outer membrane complexes in this spirochete. The present study characterized expression of PrcA, the protease complex-associated polypeptide, and the PrtP-dependent processing of PrcA that results in the two native protease complex-associated proteins PrcA1 and PrcA2.

The prcA gene identified in this study includes the sequence previously reported as ORF2 directly upstream of the gene encoding the PrtP protease component of the CTLP complex (19). ORF2 was first proposed to encode one of the two protease complex-associated proteins, based on its location adjacent to prtP, the size of its deduced protein product, and the presence within the deduced protein of an amino acid sequence identical to the N-terminal sequence one of the native CTLP complex proteins. The absence of an identifiable signal sequence on the deduced ORF2 product that could direct it to a secretory pathway was not previously addressed and led us to further examine DNA sequences upstream of ORF2. Our results showed that prcA, including ORF2 and 852 bp upstream, encodes a protein of 70 kDa with a hydrophobic N-terminal region that could serve as a membrane-targeting or translocation signal. The N-terminal region includes a potential recognition site (L-F-G-S-C, residues 20 to 24) for spirochetal signal peptidase II (15). The prediction that PrcA is acylated is consistent with the observed segregation of the entire CTLP complex to the detergent phase of Triton X-114 extracts (6).

Identification of the prcA gene as encoding a polypeptide of 70 kDa raised further issues: (i) whether this protein is in fact part of the protease complex; and (ii) if PrcA is CTLP-associated, how it might be processed to the native molecular mass. Characterization of PrcA expression in E. coli and in T. denticola parent and isogenic mutant strains demonstrated that the PrcA polypeptide is the source of both of the two smaller proteins that, together with PrtP, form the native CTLP protease complex. In addition, cleavage of PrcA to yield PrcA1 and PrcA2 appeared to be due to PrtP protease activity, since T. denticola strains CCE and CKE (both mutated in prtP) lacked PrtP activity, and neither strain cleaved the PrcA polypeptide to a native form. The 70-kDa PrcA in CCE and the 62-kDa PrcA in CKE correspond to the predicted PrcA translation products of these strains. It is likely that cleavage of PrcA to PrcA1 and PrcA2 occurs after export across the cytoplasmic membrane. Both the deduced peptide sequence and the determined N-terminal sequence of PrtP suggest that PrtP is processed to an active form subsequent to cleavage of its N-terminal signal peptide and secretion across the cytoplasmic membrane (19) and thus is unlikely be proteolytically active in the cytoplasm.

Several other members of the subtilisin group of bacterial proteases require an associated chaperone-like protein for proper translocation and maturation (20). The PrtM protein of Lactococcus lactis, a typical member of this group, is a 33-kDa putative lipoprotein required for proper maturation of the L. lactis PrtP cell envelope-associated subtilisin homologue (29). The prtM gene is located upstream of prtP in L. lactis and is transcribed from the same promoter region, although in the opposite direction. While there is no identifiable homology between L. lactis PrtM and T. denticola PrcA, our results support the hypothesis that PrcA functions similarly as a chaperone-like molecule in the T. denticola CTLP complex.

Several areas remain for future molecular characterization of this intriguing protease complex. Most importantly, the nature of the processing event requires more study. There are two potential recognition sites for PrtP protease activity in PrcA, either of which would yield proteins of the observed sizes of PrcA1 and PrcA2. A unique Pro-Phe sequence (residues 289 to 290) contains the reporter site of SAAPFNA, the chromogenic substrate used to characterize CTLP enzyme activity (19, 22, 27). The unique sequence Pro-Leu (residues 268 to 272) is also a possible cleavage site (19). Studies of cleavage of native PrcA are likely to be problematic until methods are developed to generate defined point mutations in T. denticola. No method of purifying proteolytically active PrtP separate from PrcA1 and PrcA2 has ever been reported. The extremely close association between PrtP and PrcA1 and PrcA2 suggests that this association may be required for protease activity or localization of the complex. Similarly, while we have been unable to directly demonstrate cleavage of exogenous PrcA by PrtP present in the protease complex (data not shown), it is also likely that such cleavage may be dependent on specific association and binding between PrtP and PrcA as part of the maturation process of the protease complex.

While it was not possible to directly determine the role of PrcA1 and PrcA2 in Msp expression because T. denticola isogenic mutants deficient in either or both prcA and prtP had similar Msp phenotypes and lacked CTLP activity, these strains will be useful in planned studies examining the biological role of the CTLP protease complex in the interactions between T. denticola and host cells. The present study characterized expression and processing of a putative chaperone molecule required for proper expression and activity of T. denticola...
outer membrane-associated proteins that are implicated in periodontal disease cytopathology.
