Mutants of *Salmonella enterica* lacking the RecBC function are avirulent in mice and unable to grow inside macrophages (N. A. Buchmeier, C. J. Lipps, M. Y. H. So, and F. Heffron, Mol. Microbiol. 7:933–936, 1993). The virulence-related defects of RecBC⁻ mutants are not suppressed by *sbcB* and *sbcCD* mutations, indicating that activation of the RecF recombination pathway cannot replace the virulence-related function(s) of RecBCD. Functions of the RecF pathway such as RecJ and RecF are not required for virulence. Since the RecBCD pathway, but not the RecF pathway, is known to participate in the repair of double-strand breaks produced during DNA replication, we propose that systemic infection by *S. enterica* may require RecBCD-mediated recombinational repair to prime DNA replication inside phagocytes. Mutants lacking both RecD and RecF are also attenuated in mice and are unable to proliferate in macrophages, suggesting that exonucleases V and IX provide alternative functions for RecBCD-mediated recombinational repair during *Salmonella* infection.

*Salmonella enterica* is a gram-negative bacterial pathogen that causes gastrointestinal disorders and systemic infections in humans and livestock animals (29). A hallmark of *Salmonella* pathogenesis is the capacity of the bacterium to survive and proliferate within phagocytic cells (29). In vitro and in vivo studies have provided evidence that bacterial growth inside macrophages and neutrophils is required for systemic infection (3, 8, 18, 25, 31). Phagocytic cells synthesize DNA-damaging agents such as nitric oxide and oxygen radicals (37) as mammalian defense mechanisms against pathogens; hence, *Salmonella* must face the attack of compounds that challenge genome integrity (21, 33, 37). Active functions and mechanisms that protect *Salmonella* from oxidative stress inside phagocytes have been described recently (2, 7, 38). In addition, almost a decade ago Buchmeier et al. showed that mutants of *S. enterica* lacking RecA or RecBC functions are avirulent in the murine typhoid model and highly sensitive to oxidative compounds (35). Phagocytic cells synthesize DNA-damaging agents such as nitric oxide and oxygen radicals (37) as mammalian defense mechanisms against pathogens; hence, *Salmonella* must face the attack of compounds that challenge genome integrity (21, 33, 37). Active functions and mechanisms that protect *Salmonella* from oxidative stress inside phagocytes have been described recently (2, 7, 38). In addition, almost a decade ago Buchmeier et al. showed that mutants of *S. enterica* lacking RecA or RecBC functions are avirulent in the murine typhoid model and highly sensitive to oxidative compounds (35).

Like *E. coli* and other bacterial species, *S. enterica* can perform recombination between homologous DNA molecules by means of two main processes or pathways, RecBCD and RecF (20). Each pathway has distinct DNA substrate preferences and requires a specific set of recombination functions (20). In this study, we have examined the ability of *S. enterica* recombination mutants to cause systemic infection in mice and to proliferate inside macrophages. The strains used lack recombination functions of the RecBCD pathway and/or the RecF pathway. Our data indicate that the RecBCD enzyme is the key function required for both systemic infection and growth inside macrophages. Suppressor mutations that restore recombination proficiency in RecBC⁻ mutants by activating the RecF pathway do not restore virulence, indicating that a process different from standard recombination is affected. Because the RecF pathway cannot functionally replace RecBCD-mediated recombination for the repair of double-strand DNA breaks (15, 36), the inability of RecBC⁻ *SbcB⁻* and RecBC⁻ *SbcB⁻ SbcCD⁻* mutants of *S. enterica* to grow inside macrophages may result from arrested chromosome replication upon DNA damage. We also show that the functions of the RecF pathway are not required for virulence; however, mutants lacking both RecD and RecF are avirulent, suggesting that exonuclease IX (RecJ) can substitute for the exonuclease activity of RecBCD.

Tests for virulence of *S. enterica* serovar Typhimurium recombination mutants in BALB/c mice. To identify recombination functions required for virulence in the murine typhoid model, BALB/c mice were challenged with recombination-deficient strains of *S. enterica* serovar Typhimurium (Table 1). In parallel, infections were performed with the virulent strain SV1445, a *His⁻* derivative of the mouse virulent strain SL1344 (12). The insertion *zeb-6312::Tn10dTc* carried by strains SV4189 and SV4190 is a *Tn10dTc* insertion linked to the *sbcB* locus and has no effect on virulence (data not shown). The 50% lethal doses (LD₅₀) shown in Table 2 support the following conclusions. (i) Among the single mutants, the most attenuated is the RecBC⁻ mutant, which has an oral LD₅₀ more than 10⁴-fold higher than that of the parental strain. Actually, the RecBC⁻ mutant was unable to cause the death of any animal, even at the higher doses used (7.2 × 10⁹ CFU). We also observed that strain SV4191 (recA1) was able to kill mice at doses 10 to 100 times lower than those of SV4188 (recB497::MudJ) (data not shown). The difference observed between the RecA⁻ and RecBC⁻ mutants may reflect the pleiotropy of recBC mutations; i.e., they impair growth in standard culture media and cause various kinds of DNA repair defects (1, 16, 19, 22). RecF⁻, RecJ⁻, and RecF⁻ RecJ⁻ strains were all virulent, suggesting that, aside from the RecA function, functions of the RecF pathway of recombination are not required for systemic infection. LD₅₀ trials by intraperitoneal inoculation confirmed that RecA⁻ and RecBC⁻ strains...
are the only avirulent strains among the single mutants tested (data not shown).

(ii) RecA− RecF− and RecA− RecJ− mutants were attenuated at levels similar to that of a RecA− strain, confirming that RecF and RecJ functions are not required for virulence, regardless of the presence of RecA.

(iii) A RecBC− RecF− mutant showed attenuation at a level similar to that of a RecBC− strain, thereby suggesting that the only recombination pathway required for systemic infection is that of RecBCD. A corollary is that the RecF pathway cannot be derepressed by RecBCD. A corollary is that the RecF pathway cannot provide the recombination functions required for virulence, not even when the RecBCD pathway is absent. LD₅₀ trials with RecBC− RecF− mutants were not feasible because of their low viability (11).

(iv) Unexpectedly, a RecD− RecJ− mutant turned out to be avirulent. This result suggests that either exonuclease V or IX is required for systemic infection and hence that RecF can participate in RecBCD-mediated recombinational repair in the absence of the RecD subunit. Previous observations have suggested that RecD and RecF provide alternative functions for recombinational repair of DNA damage in both Salmonella (11, 23, 27) and E. coli (39). Function redundancy may thus explain why RecD− and RecJ− single mutants are virulent (Table 2; see also reference 40).

Effect of suppressors of recB and recC mutations on the virulence of S. enterica. Mutations that suppress the recombination defect of RecBC− mutants without restoring the activities of the RecB and RecBC enzymes have been characterized for both E. coli and Salmonella (1, 16, 19). In E. coli, sbc mutations are known to activate the RecF and RecE pathways of recombination (19, 20). The prophage-associated recE gene (13) does not exist in Salmonella. Mutations in the sbcB locus of S. enterica suppress the recombination deficiency and the UV sensitivity of RecBC− mutants by activating the RecF pathway (1). If combined with mutations in another locus, sbcCD, suppression of mitomycin C sensitivity is also observed (1). RecBC− SbcB− SbcCD− mutants also regain the ability to grow normally in standard media (1). With these facts in mind, we examined the ability of sbc mutations to suppress the virulence defect of RecBC− mutants of S. enterica. Both RecBC− SbcB− and RecBC− SbcB− SbcCD− strains remained avirulent by the oral and intraperitoneal routes (Table 3). The avirulence of the RecBC− SbcB− SbcCD− mutant is specially significant, because these strains are recombination proficient in transductional tests, are resistant to both UV and mitomycin C, and do not exhibit growth defects (data not shown; see also reference 1). The inability of sbc suppressors to restore virulence in RecBC− mutants confirms the idea that the role of RecBC in Salmonella virulence cannot be performed by functions of the RecF pathway. The hypothetical nature of this role is discussed below.

Ability of recombination mutants of S. enterica to proliferate in macrophages. Growth of Salmonella inside phagocytes is a strict requirement for systemic infection (8). Furthermore, a correlation between the avirulence of S. enterica RecA− and RecBC− mutants and their impaired ability to repair DNA was established in the seminal study of Buchmeier et al.: RecA− and RecBC− mutants can grow within macrophages that do not synthesize reactive oxygen compounds (4). As expected, we also found a straightforward correlation between the virulence of S. enterica recombination mutants and their ability to proliferate

*All the recombination mutations used were null and had been isolated in strain LT2. The origin of each mutant allele is as follows: recA1 and recF522::Tn5, J. R. Roth, Department of Biology, University of Utah, Salt Lake City, Utah; sbcB21, L. Bossi, Centre de Génétique Moleculaire, Centre National de la Recherche Scientifique, Gif-sur-Yvette, France; recB497::MudJ, reference 22; recD543::Tn10::Cm, reference 25; recJ504::MudJ and recJ504::Cm, reference 23; sbcCD51, laboratory collection. The mutations to the mouse-virulent strain SV1445 was performed by transductional crosses with P22 HT (34), followed by lysogen conversion on plates (5). The recombination-deficient phenotypes of the newly constructed strains were checked using tests described elsewhere (11, 22, 23, 26, 27).

*See footnote a of Table 2. Buffering of bacterial suspensions was omitted for intraperitoneal inoculation.

* NT, not tested.
in macrophages. Unlike the virulent recombination mutants, those with virulence defects when tested in mice (RecA−, RecBC−, RecD− RecJ−, RecBC− SbcB−, and RecBC− SbcB− SbcCD−) also showed defects for intracellular proliferation within J774-A1 mouse macrophages (Fig. 1). A noteworthy observation is, however, that sbe suppressor mutations were unable to restore intracellular proliferation within macrophages. Since sbe mutations restore recombination proficiency by activating pathways other than RecBCD, our observations indicate that S. enterica requires recombinational repair via the RecBCD pathway to grow inside phagocytes. Because of the unique ability of the RecBCD pathway to repair double-strand DNA breaks (15, 17, 36), it seems logical to conclude that S. enterica relies on the RecBCD recombination pathway to repair this kind of DNA lesion inside macrophages. In fact, a recent study has shown the occurrence of double-strand breaks in bacteria growing inside J774-A1 macrophages (33).

What is the role of the RecBCD pathway in Salmonella virulence? A tight association between DNA replication and recombination in phage T4 has long been known (28). In the last 5 years, the idea that DNA replication requires recombinational repair has been extended to both bacteria (14, 32) and Saccharomyces cerevisiae (24). Whenever a double-strand DNA break is produced, recombinational repair via the RecBCD pathway is required to prime DNA synthesis and hence for the resumption of chromosome replication (17, 36). Our observation that the RecBC enzyme is required for growth inside macrophages correlates with the extreme sensitivity of RecBCD− mutants to NO (35) and with the occurrence of double-strand breaks among the DNA lesions found in E. coli cells grown inside macrophages (33). Since the RecF pathway cannot functionally replace RecBCD-mediated recombination for the repair of double-strand DNA breaks, sbeB and sbeCD suppressor mutations do not restore recombinational repair (17). Hence, the inability of RecBC− SbcB− and RecBC− SbcB− SbcCD− mutants of S. enterica to grow inside macrophages may result from arrested chromosome replication upon DNA damage.

Our finding that RecD− RecJ− mutants are avirulent and unable to grow inside macrophages seems to indicate that, in the absence of the RecD exonuclease, recombinational repair via the RecBCD pathway can be carried out with the participation of RecJ. This situation is similar to that of Rep− mutants of E. coli, which require either RecD or RecJ for double-strand break repair (36). Furthermore, there is evidence that RecJ is involved in the recovery of replication forks upon DNA damage (6) and in other RecBC-dependent recombination processes (27, 39).

In summary, we propose that S. enterica uses the RecBCD recombination pathway to repair DNA double-strand breaks produced during growth inside macrophages and that RecD and RecJ provide alternative exonuclease activities for the repair process. The absence of RecBC or both RecD and RecJ renders Salmonella avirulent. A tentative explanation, supported by abundant literature (reviewed in reference 15), may be that Salmonella needs RecBC-mediated DNA repair to prime DNA replication inside phagocytes.
